Preface

MapleMBSE Overview

MapleMBSE™ gives an intuitive, spreadsheet based user interface for entering detailed system design definitions, which include structures, behaviors, requirements, and parametric constraints.

Related Products

MapleMBSE 2018 requires the following products.

- Microsoft® Excel® 2010 Service Pack 2, Excel 2013 (updated to most recent version, for details please see the Release Notes) or Excel 2016.
- Oracle® Java® SE Runtime Environment 8.

Note: MapleMBSE looks for a Java Runtime Environment in the following order:

- 1) If you use the -vm option specified in **OSGiBridge.init** (not specified by default), MapleMBSE will use it.
- 2) If your environment has a system JRE (meaning either: JREs specified by the environment variables JRE_HOME and JAVA_HOME in this order, or a JRE specified by the Windows Registry (created by JRE installer)), MapleMBSE will use it.
- 3) The JRE installed in the MapleMBSE installation directory.

If you are using IBM® Rational® Rhapsody® with MapleMBSE, the following versions are supported:

- Rational Rhapsody Version 8.1.2 or Version 8.1.3
- Teamwork CloudTM server 18.5

Note that the architecture of the supported non-server products (that is, 32-bit or 64-bit) must match the architecture of your MapleMBSE architecture.

Customer Feedback

Maplesoft welcomes your feedback. For comments related to the MapleMBSE product documentation, contact $\underline{doc@maplesoft.com}$.

1 Introduction

1.1 Scope and Purpose of this Document

The purpose of the MapleMBSE Virtual Features Guide is to describe MapleMBSE virtual features and explain how to use them.

The intended audience for this document are users who are familiar with UML, SysML and Model-based Systems Engineering concepts and who intend to create their own MapleMBSE configuration files.

1.2 Prequisite Knowledge

To fully understand the information presented in this document the reader should be familiar with the following concepts:

- The Eclipse Modeling Framework ecore serialization. In particular, knowing how to
 use any tool of your choice to track all the eReferences independently of the eSuperTypes
- Thus, some basic concepts of Meta Object Facilty like *eClassifiers* and *eStructuralFeatures*. A correct mse configuration file has within each qualifier a concrete UML *eClassifiers* and each dimension should be accessed using a non-derived *StructuralFeature* defined in the UML.ecore or a virtual one inside this guide.
- MapleMBSE Configuration Language elements, (especially dimension and qualifiers, and the syntax for importing the MapleMBSE ecore). For more information on the MapleMBSE Configuration language, see the MapleMBSE Configuration Guide.

1.3 Motivation for Using MapleMBSE Virtual Features

SysML provides a high level of abstraction to cover as many modeling scenarios as possible with the diagrams offered. It is a powerful and complex language that is extremely difficult to master because of its complexity (there are hundreds of pages of technical specifications for SysML).

Many different concrete and abstract *Classifiers*, with very specific semantics, are part of the SysML technical specifications. These *Classifiers* should not be used interchangeably. Even "linking" elements changes depending on the "linked" elements. For example, SysML *Associations* are to *Classes* as *Connectors* are to Ports, or, what *ControlFlows* can be for *ActivityNodes*. However, these elements are not interchangeable.

An end user, defined as a user who will be updating model information using the MapleMBSE spreadsheet interface but likely will not be involved in creating or editing configuration files, who interested in taking advantage of the modeling capabilities of

SysML, should not need to know its complexities. MapleMBSE helps to hide this complexity from the end user, through virtual features. They are called virtual features because, although they extend the capabilities of native SysML, they themselves are not part of SysML.

With the right choice of labels within an Excel template and a well designed configuration (.mse) file that implements MapleMBSE virtual features, an end user can enter a couple of inputs in a spreadsheet and create *Blocks* and the Associations linking them, or Ports and Connectors, or other combinations of elements.

For example, consider the following code snippet from a MapleMBSE configuration file in the figure below. This figure illustrates the scenario where a configuration file is designed without the use of virtual features to represent SysML *Associations* between *Blocks*.

Notice in the generated Excel worksheet, the number of inputs required of the end user to represent the *Assocation* between **Customer** and **Product**. This requires knowledge of SysML on the part of the end user.

```
record dim [Model] {
                                                                                        Creating a configuration file without MapleMBSE virtual
                                                                                          features results in an excel file that requires more
                                                                                        input from the end user and requires the end user to
                                                                                          know SysML to add elements to the spreadsheet
    alternative {
             record dim /packagedElement[Class | mse::metaclassName="SysML::Blocks::Block"] {
                 key column /name as cName
            record dim /ownedAttribute[Property] {
                 kev column /name as pName
                 reference-query .type @ typeRef
                 reference-decomposition typeRef = bsc {
                      foreign-key column blockName as blockRef
                 reference-query .association @ associationRef
                 reference-decomposition associationRef = asc
                                                                                 Model Customer
                                                                                                            oughtitem
                                                                                                                     Product
                                                                                                                                      purchases
                      foreign-key column associationName as ascRef
        record dim /packagedElement[Association] {
             key column /name as aName
worksheet-template Template2(gch: Schema2) (
    vertical table tabl at (2, 1) = sch \{
        key field mName : String
key field cName : String
        key field aName : String
key field pName : String
        key field blockRef : String
        key field ascRef : String
```

Now consider an example that represents the same Association between Customer and Product, as shown in the figure below. This time, the configuration file is designed using the MapleMBSE virtual features, specifically, the associatedProperty virtual feature. Notice, the only inputs required of the end user are the two SysML *Blocks*, **Customer** and **Product**. The cross-references need for the Association are completed automatically.

```
1 synctable-schema Schema (bsc: BlockSchema) {
       record dim [Class | mge::metaclassName="SysML::Blocks::Block"] {
           key column /name as cName
                                                                                          Creating a configuration file that uses MapleMBSE
                                                                                          virtual features results in an excel file that requires
                                                                                         much less input from the end user and the end user
       dim /ownedAttribute[Property].mse::associatedProperty[Class] @ classRef {
                                                                                          does not need to know uml to create Association.
       reference-decomposition classRef = bsc (
               foreign-key column blockName as refCName
                                                                                                               Target block
                                                                                                      Block
                                                                                                      Product
                                                                                                     Product Customer
   worksheet-template Template(sch: Schema) {
                                                                                                      Customer
        vertical table tab1 at (2, 1) = sch {
                                                                                                      Customer Product
            key field cName : String
            key field refCName : String
```

1.4 Importing the MapleMBSE Ecore

Loading MapleMBSE virtual features is analogous to the way you would load UML Structural Features using UML Ecore. The corresponding MapleMBSE Configuration language uses import-ecore.

The general syntax is

import-ecore "URI"

For example, to specify the NoMagic ecore:

"http://www.nomagic.com/magicdraw/UML/2.5"

To specify the MapleMBSE ecore:

"http://maplembse.maplesoft.com/common/1.0"

You must create an alias for the ecore using the syntax:

import-ecore "URI" as Alias

For example, to specify an alias for the MapleMBSE ecore:

import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse

This allows you to use the short form, mse, instead of the whole syntax.

1.5 General Syntax for the MapleMBSE Virtual Features

The general syntax for the virtual features is

```
[./]?alias::virtualfeature
```

The first character can be a dot, a forward slash, or a blank. There is no strict rule of thumb for this. For specific syntax, see the Syntax subsection for each virtual feature.

alias - This is the alias for the ecore import

virtual feature - This is the virtual feature name you want to use, for example, associated Property.

1.6 List of Virtual Features

The MapleMBSE virtual features can be grouped into five categories:

Stereotypes (page 5). This group includes the metaclassName and featureName virtual features.

Associations (page 11) This group includes the associated Property, direct Associated Property, and other Associated End virtual features.

Connectors (page 19) This group includes the connected Property Or Port and other Connector End virtual features.

Dependencies (page 23) This group includes the clientDependencies and supplier—Dependencies virtual features.

*Util (page 27)*This group includes the multiplicityProperty virtual feature.

2 Stereotypes

SysML can be explained as a subset of elements defined in the UML specifications plus some additional features not included in UML. One of these features is a *Stereotype*. *Stereotypes* are applied to those elements adding extra meaning or modeling semantics. MapleMBSE offers several virtual features to apply *Stereotypes* and navigate their extended modeling capacities.

2.1 metaclassName

Description

Use the **metaclassName** virtual feature to apply *Stereotypes* while creating elements using MapleMBSE. To use this virtual feature you need to identify the qualified name of the *Stereotype* that you want to apply and whether the element is compatible with that stereotype.

Syntax

Any *Element* of the *Model* can have a list of *appliedStereotype* but only certain *Stereotypes* should be applied to certain *Element*. This is one of the few virtual features that is used as a filter inside the qualifier and it does not require a dot or slash notation prior to the alias. The **metaclassName** virtual feature must be followed by an equals simbol and the qualified name of the *Stereotype* between quotation mark.

alias::metaclassName="qualified::name"

It is important to note that this qualified name is basically a path and the name that identifies uniquely each *Stereotype*, and each substring is concatenated with a double colon notation.

Using the metaclassName Virtual Feature

The following steps Illustrate what you need to do to use AssociatedProperty virtual feature:

- 1. The MapleMBSE ecore is imported and its alias is mse.
- 2. Two data-sources are used for this example with metaclassName to filter *Blocks* and *Requirements*. **Note**: both of those SysML concept are UML Classes but with different Stereotypes.
- 3. Defining synctable-schemas, one for *Blocks* and another for *Requirements*. **Note**: To avoid problems with MapleMBSE it is a good practice to use the same qualifier and *Stereotype* filter in the data-source and the first dimension of the schema.
- Complete the rest of the configuration as usual: worksheet-templates, synctable and workbook.

Example

The following example showcases how to use metaclassName to create *Classes* applying 2 different *Stereotypes*.

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source blocks = Root/packagedElement[Class |
mse::metaclassName="SysML::Blocks::Block"]
data-source requirements = Root/packagedElement[Class |
mse::metaclassName="SysML::Requirements::Requirement"]
synctable-schema BlockSchema {
record dim [Class | mse::metaclassName="SysML::Blocks::Block"] {
 key column /name as bName
}
}
synctable-schema RequirementSchema {
record dim [Class | mse::metaclassName="SysML::Requirements::Requirement"]
 key column /name as rName
}
worksheet-template BlockTemplate (bsc: BlockSchema) {
vertical table tabl at (1, 1) = bsc {
 key field bName: String
worksheet-template RequirementTemplate(rsc: RequirementSchema) {
vertical table tabl at (1, 1) = rsc {
 key field rName: String
}
synctable blockTable = BlockSchema<blocks>
synctable requirementTable = RequirementSchema<requirements>
workbook {
worksheet BlockTemplate(blockTable)
worksheet RequirementTemplate(requirementTable)
```

2.2 featureName

Description

As mentioned in the introduction of this section, once you applied a *Stereotype* to any *Element*, you are changing its semantics and extending it. Use featureName to access those extended properties stored in *Slots* using their qualified names.

The class diagram in Figure 2.1 (page 7) shows the different EClasses that need to be queried in order to access those Slots, remember that Element is an abstract EClass and it should not be used as the qualifier. Basically all elements in a Model implement Element, thus EClasses like Class have the structural feature appliedStereotypeInstance to query InstanceSpecification.

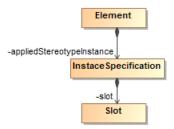

Figure 2.1: A The appliedStereotypeInstance Structure

Syntax

Use featureName the same way metaclassName is used within a qualifier as a filter, meaning that no dot or slash notations are needed before the alias. It expected, follwing the virtual feature, an equal symbol and a string between quotation marks; this string is the qualified name of the property to access.

```
alias::featureName="qualified::name"
```

This qualified name is similar to the one used to identify the *Stereotype* but it differs slightly at the end with an extra information concatenated to identity a single extension. As mentioned before this virtual feature is usable while querying a *Slot* inside a *InstanceSpecification* inside an concrete *Element*, but you must also know that this *Element* must be filtered by meta-className with the qualified name that identifies the *Stereotype*.

Using the featureName Virtual Feature

To access extra Properties added after applying a Stereotype:

- 1. Import the MapleMBSE ecore.
- 2. Inside a syntable-schema navigate to a *MultiplicityElement*, in this case, /ownedAt-tribute[Property] within a Class.
- 3. Within that dimension, define a regular column using /mse::multiplicityProperty.
- 4. Complete the rest of the configuration as usual: worksheet-templates, synctable and workbook.

Example

The following example illustrates how to access extra *Properties* added after applying a *Stereotype*.

- 1. Import MapleMBSE ecore, for this example use mse as the alias.
- 2. Create a data-source using the metaclassName virtual feature mentioned before to filter *Requirements*.
- 3. Define a synctable-schema for *Requirements*. **Note**: use the same qualifier and *Stereotype* for the first dimension that for the data-source.
- 4. To access the SysML::Requirements::Requirement::Text *Property* added to a *Class* after applying the Requirement Stereotype you must:
 - 1. Navigate appliedStereotypeInstance to get an InstanceSpecification.
 - 2. Then *slot* to recover all the *Slots* within the *InstanceSpecification*
 - 3. Use featureName with the Slot qualifier to filter the Property that you want to access

Note: The qualified name of that *Property* is the name of the qualified *Stereotype* plus 2 colons and the name of the *Property*.

```
Stereotype: SysML::Requirements::Requirement
Property: SysML::Requirements::Requirement::Text
```

 Complete the rest of the configuration as usual: worksheet-templates, synctable and workbook.

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse

data-source Root[Model]
data-source requirements = Root/packagedElement[Class |
mse::metaclassName="SysML::Requirements::Requirement"]
```

```
synctable-schema RequirementSchema {
record dim [Class | mse::metaclassName="SysML::Requirements::Requirement"]
 key column /name as rName
 column
/appliedStereotypeInstance[InstanceSpecification]/slot[Slot|mse::featureName=
     "SysML::Requirements::Requirement::Text"]/value[LiteralString]/value
       as spec
}
}
worksheet-template RequirementTemplate(rsc: RequirementSchema) {
vertical table tabl at (1, 1) = rsc {
 key field rName: String
field spec: String
}
}
synctable requirementTable = RequirementSchema<requirements>
workbook {
worksheet RequirementTemplate(requirementTable)
```

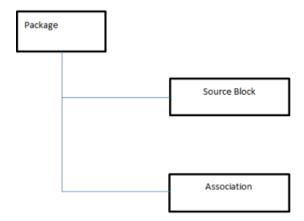

3 Associations

An *Association* between two *Blocks* creates cross references for two UML *Classes* with SysML *Block Stereotypes* (<<bl/>block>>) to one *Association* using two properties and also makes some cross references, like *Type* and *Association*, within those properties.

3.1 associatedProperty

Description

In MagicDraw, with a couple clicks from one block to another, all of these elements are correctly created. Similarly in MapleMBSE, the associatedProperty virtual feature provides the ability to connect two SysML *Blocks*, creating a bidirectional *Association* at the same hierarchicallevel in the diagram as the source *Block*.

When MapleMBSE queries the model, the associatedProperty returns the target *Block* (the *Block* that is related to a *Property* through an *Association*).

Syntax

The general syntax for using the associatedProperty virtual feature is as follows:

```
.alias::associatedProperty
```

Where alias is the alias you assigned to the MapleMBSE ecore. For more information on assigning aliases, see *Importing the MapleMBSE Ecore (page 3)*.

11

The associatedProperty virtual feature must be used when querying the *Property* of a *Block*.

Using the associatedProperty Virtual Feature

The following example Illustrates what you need to do to use AssociatedProperty virtual feature.

- 1. In line two, the **maplembse ecore** is imported with an alias.
- 2. Use an ownedAttribute[Property] as the queried dimension.
- 3. Make a reference-query to a class using mse::associatedProperty.
- 4. Complete the reference-decomposition.

Example

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source structurePkg = Root/packagedElement[Package]
data-source clss = structurePkg/packagedElement[Class]
synctable-schema ClassTableSchema {
dim [Class] {
 key column /name as ClassName
}
synctable-schema ClassTreeTableSchema(blocks: ClassTableSchema) {
record dim [Class] {
 key column /name as className1
dim /ownedAttribute[Property].mse::associatedProperty[Class] @ cls {
 reference-decomposition cls = cts {
 foreign-key column ClassName as referredClassName
}
synctable classTableSchema = ClassTableSchema<clss>
synctable classTreeTableSchema = ClassTreeTableSchema<clss>(classTableSchema)
worksheet-template ClassTable(cts: ClassTableSchema) {
vertical table tabl at (6, 2) = cts {
```

```
key field ClassName : String
 key field Name4 : String
worksheet-template ClassTreeTable(ctt: ClassTreeTableSchema) {
vertical table tab1 at (6, 2) = ctt {
 key field ClassName1 : String
 key field referredClassName : String
workbook{
worksheet ClassTable(classTableSchema)
worksheet ClassTreeTable(classTreeTableSchema)
```

3.2 directedAssociatedProperty

Description

To create Associations with navigability in one direction MapleMBSE uses directed AssociatedProperty, using this virtual feature links two Classes and adds a Property to the source Block and other Property to an Association.

Based on the aggregation value we can use this virtual feature to create Association, Aggregation and Composition with direction.

Syntax

The general syntax for using the directedAssociatedProperty virtual feature is as follows:

```
.alias::directedAssociatedProperty
```

Where alias is the alias you assigned to the MapleMBSE ecore (hyperlink to above).

The directedAssociatedProperty virtual feature must be used when querying the Property of a Block.

Using the directAssociatedProperty Virtual Feature

The following example Illustrates what you need to do to use directedAssociated-Property.

- 1. In line two, the **maplembse ecore** is imported with an alias.
- 2. Use an ownedAttribute[Property] as the queried dimension.
- 3. Make a reference-query to a class using mse::directedAssociatedProperty.
- 4. Complete the reference-decomposition.

Example

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source structurePkg = Root/packagedElement[Package]
data-source clss = structurePkg/packagedElement[Class]
synctable-schema ClassTableSchema {
dim [Class] {
 key column /name as ClassName
synctable-schema ClassTreeTableSchema(blocks: ClassTableSchema) {
record dim [Class] {
 key column /name as className1
dim /ownedAttribute[Property].mse::directedAssociatedProperty[Class] @ cls
 reference-decomposition cls = cts {
 foreign-key column ClassName as referredClassName
 }
synctable classTableSchema = ClassTableSchema < clss >
synctable classTreeTableSchema = ClassTreeTableSchema<clss>(classTableSchema)
worksheet-template ClassTable(cts: ClassTableSchema) {
vertical table tabl at (6, 2) = cts {
 key field ClassName : String
 key field Name4 : String
```

```
worksheet-template ClassTreeTable(ctt: ClassTreeTableSchema) {
vertical table tabl at (6, 2) = ctt {
 key field ClassName1 : String
 key field referredClassName : String
}
workbook{
worksheet ClassTable(classTableSchema)
worksheet ClassTreeTable(classTreeTableSchema)
```

3.3 otherAssociatedEnd

Description

other Association End is used in the case when two classifiers has to be linked and the information about the properties of these classifiers are owned by the association and not the classifiers themselves, such as in the case of UseCase diagram where assocaition exist between an actor and usecase and these two classifiers does not own any property that defines the other classifier

Syntax

The general syntax for using the otherAssociationEnd virtual feature is as follows:

```
.alias::otherAssociationEnd
```

Where alias is the alias you assigned to the MapleMBSE ecore (hyperlink to above).

The otherAssociationEnd virtual feature must always be used when querying a Class

Using the otherAssociatedEnd Virtual Feature

The following example Illustrates what you need to do to use otherAssociationEnd.

- 1. In line two, the **maplembse ecore** is imported with an alias.
- 2. Use when a Class as the queried dimension.
- 3. Make a reference-query to a class using mse::otherAssociationEnd, unlike other virtual features in this section other Association End should not be used when a property is querried.

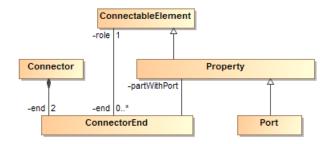

4. Complete the reference-decomposition.

Example

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source useCasePkg = Root/packagedElement[Package]
data-source actors = useCasePkg/packagedElement[Actor]
data-source useCases = useCasePkg/packagedElement[UseCase]
synctable-schema ActorsTable {
record dim [Actor] {
 key column /name as Actor
synctable-schema UseCasesTable(ac:ActorsTable) {
record dim [UseCase] {
 key column /name as Name
 reference-query .mse::otherAssociationEnd[Actor] @ actor
 reference-decomposition actor = ac {
 foreign-key column Actor as Actor
}
synctable actorsTable = ActorsTable<actors>
synctable useCasesTable = UseCasesTable<useCases>(actorsTable)
worksheet-template Actors(ac: ActorsTable) {
vertical table tab1 at (5, 3) = ac {
 key field Actor : String
}
}
worksheet-template UseCases(auct: AssociatedUseCasesTable) {
vertical table tabl at (5, 3) = auct {
 key field Name : String
 key field Actor : String
}
}
workbook {
```

```
worksheet Actors(actorsTable)
worksheet UseCases(useCasesTable)
}
```

4 Connectors

A Connector is used to link ConnectableElements (for example, Ports or Properties) of a Class through a ConnectorEnd. A Connector has two ConnectorEnds.

Based on the connection between *Properties* of a *Class* the connection can be of two types: *Delegation* (connecting *Ports* or *Properties* from the system to *Ports* or *Properties* inside a *Class*) or *Assembly* (connecting *Ports* or *Properties* within a *Class*).

4.1 connectedPropertyOrPort

Description

To achieve this connection MapleMBSE uses connectedPropertyOrPort virtual feature.

The connectorPropertyOrPort virtual feature connects *Ports* or *Properties* of a *Class*. It automatically detects the kind of relation required between the *Properties* being connected and creates the appropriate connection.

When MapleMBSE queries the model, the connectedPropertyOrProt return the list of target properties.

Syntax

The general syntax for using the connectedPropertyOrPort virtual feature is as follows:

.alias::connectedPropertyOrPort

Where the alias is alias you assigned to MapleMBSE ecore.

When the connection is created through connectedPropertyOrPort, the owner of the connected *Property* is determined automatically by MapleMBSE, regardless of whether this is a *Delegation* or *Assembly* type connection.

Using the connectedPropertyOrPort virtual feature

In general, to use the connectedPropertyOrPort virtual feature:

- 1. First, import the MapleMBSE ecore with alias
- 2. Use an ownedAttribute[Property] as the queried dimension.
- 3. Make a reference-query to a property using mse::connectedPropertyOrPort.
- 4. Complete the reference-decomposition.

Example

A specific example of how to use the ConnectedPropertyOrPort virtual feature is shown below.

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
synctable-schema BlocksTable {
        record dim [Class|mse::metaclassName="SysML::Blocks::Block"] {
                key column /name as BlockName
        dim /ownedAttribute[Property] {
               key column /name as PropertyName
synctable-schema ConnectedPropertyOrPortTable(bT: BlocksTable) {
       record dim [Class|mse::metaclassName="SysML::Blocks::Block"] {
               key column /name as className
       record dim /ownedAttribute[Property] {
               key column /name as ParentPort
       record dim .mse::connectedPropertyOrPort @ cls {
                reference-decomposition cls = bT {
                foreign-key column BlockName as referredClassName
                foreign-key column PortName as referredPortName
       }
```

4.2 otherConnectorEnd

Description

To achieve this connection MapleMBSE also use otherConnectorEnd virtual feature. This virtual feature can connect between ports or properties of a class, otherConnectorEnd automatically create the relation required between the properties being connected and creates appropriate connection.

When MapleMBSE queries the model, the otherConnectorEnd return the list of connectorEnds which is associated with the property.

Syntax 1 4 1

The general syntax for using the otherConnectorEnd virtual feature is as follows:

```
.alias::otherConnectorEnd
```

Where the alias is the alias you assigned to the MapleMBSE ecore.

When the connection is created using otherConnectorEnd, the owner of the connected Property is determined automatically by MapleMBSE, regardless of whether this is a Delegation or Assembly type connection.

Using the otherConnectorEnd Virtual Feature

How to use the otherConnectorEnd virtual feature is shown in the example below:

- 1. First, import the MapleMBSE ecore with an appropriate alias
- 2. Use an ownedAttribute [Property] as the queried dimension.
- 3. Make a reference-query to a property using mse::otherConnectorEnd.
- 4. Complete the reference-decomposition.

Example

A specific example of how to use the otherConnectorEnd virtual feature is shown below

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
synctable-schema BlocksTable {
        record dim [Class|mse::metaclassName="SysML::Blocks::Block"] {
                key column /name as blockName
       dim /ownedAttribute[Property] {
                 key column /name as propertyName
```

5 Dependencies

A *Dependency* is used between two model elements to represent a relationship where a change in one element (the supplier element) results in a change to the other element (client element).

A *Dependency* relation can be created between any *namedElement*. Different kinds of *Dependencies* can be created between the model elements such as *Refine*, *Realization*, *Trace*, *Abstraction* etc.,

5.1 clientDependencies

Description

The clientDependencies virtual feature creates a relation between the client being the dependent and supplier who provides further definition for the dependent.

Syntax

The general syntax for using the clientDependencies virtual feature is as follows:

```
/mse::clientDependencies
```

This virtual feature is used while querying a Class that has to be assiged as client to the dependency that is being created and is used in a following dimension the class that is being querried.

Where alias is the alias you assigned to the MapleMBSE ecore.

Using the clientDependencies Virtual Feature

In general, the following steps outline how to use clientDependencies:

- 1. It should be used when a named element is queried
- 2. Information about the type of relationship is specified as [Dependency], [Abstraction] etc.,
- 3. When querying the model element with mse::clientDependencies, the reference decomposition should be to a supplier element.

Example

The example below is an illustration of how to use the clientDependencies virtual feature.

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
```

```
data-source Root[Model]
data-source package = Root/packagedElement[Package|name="Package"]
data-source act = package/packagedElement[Activity]
data-source cls = package/packagedElement[Class]
synctable-schema ActivityTableSchema {
record dim [Activity] {
 key column /name as ActName
synctable-schema ClassAbstractionTableSchema(acts:ActivityTable) {
record dim [Class] {
 key column /name as ActName1
record dim /mse::clientDependencies[Dependency] {
 key reference-query .supplier @ refDecomp
     reference-decomposition refDecomp = reqs {
  foreign-key column ActName as AbsName
}
synctable activityTableSchema = ActivityTableSchema<act>
synctable classAbstractionTableSchema =
ClassAbstractionTableSchema<cls>(ActivityTable)
worksheet-template ActivityTable(cts:ActivityTableSchema) {
vertical table tab1 at (4,5) = cts{}
 key field ActName : String
}
worksheet-template ClassAbstractionTable(cds:ClassAbstractionTableSchema){
vertical table tabl at (4,5) = cds{}
 key field ActNamel : String
 key field AbsName : String
}
workbook{
worksheet ActivitiesTable (ActivityTable)
worksheet ClassAbstractionTable(classAbstractionTableSchema)
```

5.2 supplier Dependencies

Description

Similar to clientDependencies, supplierDependencies is used to create a relation between two named elements. The only difference between the two virtual features is supplierDependencies is used when the relationship has to be made from supplier to client instead of client to supplier, as in the case of client Dependencies.

Syntax

The general syntax for using the supplierDependencies virtual feature is as follows:

```
/mse::supplierDependencies
```

This virtual feature is used while querying a Class that has to be assiged as supplier to the dependency that is being created and is used in a dimension following the class that is being querried.

Where alias is the alias you assigned to the MapleMBSE ecore.

Using the supplierDependencies Virtual Feature

The following example Illustrates what you need to do to use supplierDependencies

- 1. It should be used when a named element is being queried.
- 2. Information about the type of relationship is specified as [Dependency], [Abstraction] etc..
- 3. When querrying the model element with mse::supplierDependencies the reference decomposition should be to a client element.

Example

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source package = Root/packagedElement[Package|name="Package"]
data-source cls =
package/packagedElement[Class|mse::metaclassName="SysML::Requirements::Requirement"]
synctable-schema RequirementsTableSchema {
record dim [Class|mse::metaclassName="SysML::Requirements::Requirement"]
 key column /name as ReqName
```

```
synctable-schema RequirementsDerivesTableSchema(reqs:RequirementsTable) {
record dim [Class|mse::metaclassName="SysML::Requirements::Requirement"]
 key column /name as ReqName1
record dim
/mse::supplierDependencies[Abstraction|mse::metaclassName="SysML::Requirements::DeriveReqt"]
 key reference-query .client @ reqDecomp
 reference-decomposition reqDecomp = reqs {
   foreign-key column ReqName as DeriveName
 }
synctable requirementsTableSchema = RequirementsTableSchema<cls>
synctable requirementsDerivesTableSchema =
RequirementsDerivesTableSchema<cls>(requirementsTable)
worksheet-template ReqClassTable(cts:RequirementsTableSchema) {
vertical table tab1 at (4,5) = cts{}
 key field Name : String
worksheet-template ReqClassDependency(cds:RequirementsDerivesTableSchema) {
vertical table tab1 at (4,5) = cds{}
 key field Name1 : String
 key field DeriveName : String
}
workbook{
worksheet ReqClassTable(requirementsTableSchema)
worksheet ReqClassDependency(requirementsDerivesTableSchema)
```

6 Util

This section contains all other virtual features that do not create elements but offer a better alternative to access and map model information.

6.1 multiplicityProperty

Description

The UML specification contains several *MultiplicityElements* like *Properties* that have *upper* and *lower* features to describe their multiplicity. Use the **multiplicityProperty** virtual feature to make a configuration that translates a string into those *upper* and *lower* values and the other way around.

This virtual feature recognizes the UML commonly used notation for multiplicity (e.g. 0..*). Supporting this notation makes MapleMBSE much easier to use without adding complexity and thus the final user has less to input into Excel.

Syntax

The general syntax for using the multiplicityProperty virtual feature is as follows:

```
/alias::multiplicityProperty
```

Where the alias is the alias you assigned to the MapleMBSE ecore.

This virtual feature can only be used while querying a concrete *EClass* implementing a *MultiplicityElement* like a *Property* or a *Pin*. A slash notation is needed prior to the alias, the 2 colons, and **multiplicityProperty**.

As mention previously multiplicityProperty uses a string to represent the multiplicity, meaning that this particular virtual feature cannot being used as a dimension with a qualifier. It is intended to be used only at a column declaration.

Using the multiplicityProperty Virtual Feature

The following example shows you how to map the multiplicity of a concrete *MultiplicityElement* like *Property* and a string.

- 1. Import the MapleMBSE ecore, as usual the alias used is mse
- 2. Inside a syntable-schema navigate to a *MultiplicityElement*, in this case /ownedAttrib-ute[Property] within a Class
- 3. Within that dimension, define a regular column using /mse::multiplicityProperty

4. Complete the rest of the configuration as usual: worksheet-templates, synctable and workbook

Example

```
import-ecore "http://www.nomagic.com/magicdraw/UML/2.5"
import-ecore "http://maplembse.maplesoft.com/common/1.0" as mse
data-source Root[Model]
data-source classes = Root/packagedElement[Class]
synctable-schema Schema {
record dim [Class] {
 key column /name as cName
}
record dim /ownedAttribute[Property] {
 key column /name as pName
 column /mse::multiplicityProperty as multiplicity
worksheet-template Template(sch: Schema) {
vertical table tabl at (2, 2) = sch \{
 key field cName : String
 key field pName : String
 field multiplicity : String
 sort-keys cName, pName
}
synctable tableProperty = Schema<classes>
workbook {
worksheet Template (tableProperty)
```
